TODO:

- Define a loss function that quantifies our unhappiness with the scores across the training data.
- Come up with a way of efficiently finding the parameters that minimize the loss function. (optimization)

E.g. Suppose that we found a W such that L = 0. Is this W unique?

No! 2W is also has L = 0! How do we choose between W and 2W?

$$L(W) = \underbrace{\frac{1}{N} \sum_{i=1}^{N} L_i(f(x_i, W), y_i)}_{}$$

Data loss: Model predictions should match training data

$$L(W) = \underbrace{\frac{1}{N} \sum_{i=1}^{N} L_i(f(x_i, W), y_i) + \lambda R(W)}_{i=1}$$

 λ = regularization strength (hyperparameter)

Data loss: Model predictions should match training data

Regularization: Prevent the model from doing *too* well on training data

$$L(W) = \underbrace{\frac{1}{N} \sum_{i=1}^{N} L_i(f(x_i, W), y_i) + \lambda R(W)}_{i=1}$$

 λ = regularization strength (hyperparameter)

Data loss: Model predictions should match training data

Regularization: Prevent the model from doing *too* well on training data

Simple examples

L2 regularization:
$$R(W) = \sum_{k} \sum_{l} W_{k,l}^2$$

L1 regularization: $R(W) = \sum_{k} \sum_{l} |W_{k,l}|$

Elastic net (L1 + L2):
$$R(W) = \sum_k \sum_l \beta W_{k,l}^2 + |W_{k,l}|$$

$$L(W) = \underbrace{\frac{1}{N} \sum_{i=1}^{N} L_i(f(x_i, W), y_i) + \lambda R(W)}_{i=1}$$

 λ = regularization strength (hyperparameter)

Data loss: Model predictions should match training data

Regularization: Prevent the model from doing *too* well on training data

Simple examples

L2 regularization:
$$R(W) = \sum_k \sum_l W_{k,l}^2$$

L1 regularization: $R(W) = \sum_k \sum_l |W_{k,l}|$
Elastic net (L1 + L2): $R(W) = \sum_k \sum_l \beta W_{k,l}^2 + |W_{k,l}|$

More complex:

Dropout
Batch normalization
Stochastic depth, fractional pooling, etc

$$L(W) = \underbrace{\frac{1}{N} \sum_{i=1}^{N} L_i(f(x_i, W), y_i) + \lambda R(W)}_{i=1}$$

 λ = regularization strength (hyperparameter)

Data loss: Model predictions should match training data

Regularization: Prevent the model from doing *too* well on training data

Why regularize?

- Express preferences over weights
- Make the model *simple* so it works on test data
- Improve optimization by adding curvature

Regularization: Expressing Preferences

$$x = [1, 1, 1, 1]$$

$$w_1 = [1, 0, 0, 0]$$

$$w_2 = [0.25, 0.25, 0.25, 0.25]$$

$$w_1^T x = w_2^T x = 1$$

L2 Regularization

$$R(W) = \sum_k \sum_l W_{k,l}^2$$

Regularization: Expressing Preferences

$$x=[1,1,1,1]$$

$$w_1 = [1, 0, 0, 0]$$

$$w_2 = [0.25, 0.25, 0.25, 0.25]$$

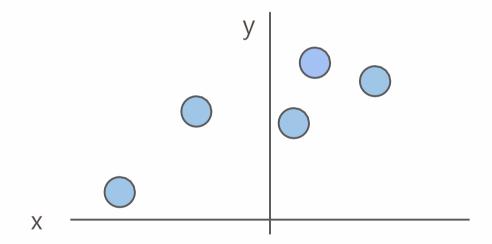

$$w_1^T x = w_2^T x = 1$$

L2 Regularization

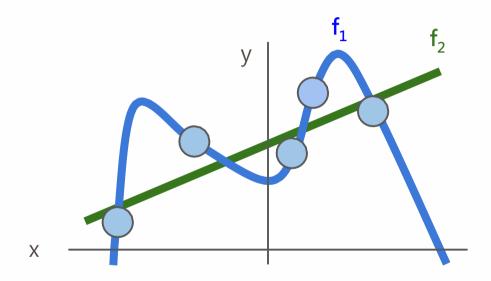

$$R(W) = \sum_k \sum_l W_{k,l}^2$$

L2 regularization likes to "spread out" the weights

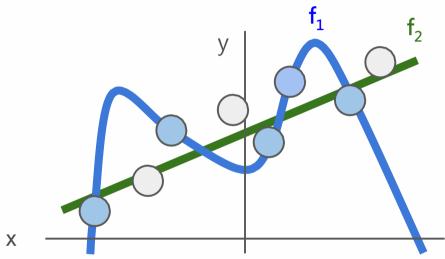

Regularization: Prefer Simpler Models

Regularization: Prefer Simpler Models

Regularization: Prefer Simpler Models

Regularization pushes against fitting the data *too* well so we don't fit noise in the data

Softmax vs. SVM

Softmax vs. SVM

$$L_i = -\log(rac{e^{sy_i}}{\sum_j e^{s_j}})$$
 $L_i = \sum_{j
eq y_i} \max(0, s_j - s_{y_i} + 1)$

Softmax vs. SVM

$$L_i = -\log(rac{e^{sy_i}}{\sum_j e^{s_j}})$$

$$L_i = \sum_{j
eq y_i} \max(0, s_j - s_{y_i} + 1)$$

assume scores:

[10, -2, 3]
[10, 9, 9]
[10, -100, -100]
and
$$y_i = 0$$

Q: What is the softmax loss and the SVM loss if I double the correct class score from 10 -> 20?

Softmax loss does not change!!

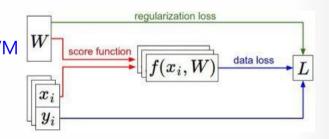

Recap: How do we find the best W?

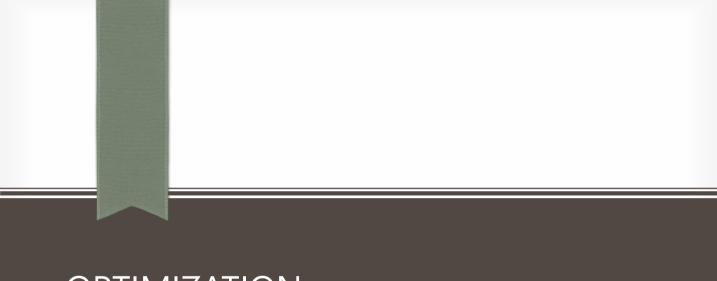

- We have some dataset of (x,y)
- We have a **score function**:
- We have a loss function:

$$L_i = -\log(rac{e^{sy_i}}{\sum_j e^{s_j}})$$
 Softmax $L_i = \sum_{j
eq y_i} \max(0, s_j - s_{y_i} + 1)$ SVM

$$L = rac{1}{N} \sum_{i=1}^{N} L_i + R(W)$$
 Full loss

OPTIMIZATION

Walking man image is CC0 1.0 public domain

Strategy #1: A first very bad idea solution: Random search

```
# assume X train is the data where each column is an example (e.g. 3073 x 50.000)
# assume Y train are the labels (e.g. 1D array of 50,000)
# assume the function L evaluates the loss function
bestloss = float("inf") # Python assigns the highest possible float value
for num in xrange(1000):
  W = np.random.randn(10, 3073) * 0.0001 # generate random parameters
  loss = L(X train, Y train, W) # get the loss over the entire training set
  if loss < bestloss: # keep track of the best solution
    bestloss = loss
    hestW = W
  print 'in attempt %d the loss was %f, best %f' % (num, loss, bestloss)
# prints:
# in attempt 0 the loss was 9.401632, best 9.401632
# in attempt 1 the loss was 8.959668, best 8.959668
# in attempt 2 the loss was 9.044034, best 8.959668
# in attempt 3 the loss was 9.278948, best 8.959668
# in attempt 4 the loss was 8.857370, best 8.857370
# in attempt 5 the loss was 8.943151, best 8.857370
# in attempt 6 the loss was 8.605604, best 8.605604
# ... (trunctated: continues for 1000 lines)
```

Lets see how well this works on the test set...

```
# Assume X_test is [3073 x 10000], Y_test [10000 x 1]
scores = Wbest.dot(Xte_cols) # 10 x 10000, the class scores for all test examples
# find the index with max score in each column (the predicted class)
Yte_predict = np.argmax(scores, axis = 0)
# and calculate accuracy (fraction of predictions that are correct)
np.mean(Yte_predict == Yte)
# returns 0.1555
```

15.5% accuracy! not bad! (SOTA is ~98%)

Strategy #2: Follow the slope

Strategy #2: Follow the slope

In 1-dimension, the derivative of a function:

$$rac{df(x)}{dx} = \lim_{h o 0} rac{f(x+h) - f(x)}{h}$$
 $rac{df(x)}{dx} = \lim_{h o 0} rac{f(x+h) - f(x-h)}{2h}$

In multiple dimensions, the **gradient** is the vector of (partial derivatives) along each dimension

The slope in any direction is the **dot product** of the direction with the gradient

The direction of steepest descent is the negative gradient

current W:

Numeric Gradient

- Slow! Need to loop over all dimensions
- Approximate

loss 1.25347

The loss is just a function of W:

$$egin{aligned} L &= rac{1}{N} \sum_{i=1}^N L_i + \sum_k W_k^2 \ L_i &= \sum_{j
eq y_i} \max(0, s_j - s_{y_i} + 1) \ s &= f(x; W) = Wx \end{aligned}$$

want $\nabla_W L$

The loss is just a function of W:

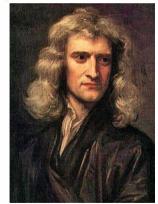

$$L = \frac{1}{N} \sum_{i=1}^{N} L_i + \sum_k W_k^2$$

$$L_i = \sum_{j
eq y_i} \max(0, s_j - s_{y_i} + 1)$$

$$s = f(x; W) = Wx$$

want $\nabla_W L$

Use calculus to compute an analytic gradient

current W:

[0.34,-1.11, 0.78, 0.12, 0.55, 2.81, -3.1, -1.5, 0.33,...] loss 1.25347 gradient dW:

In summary:

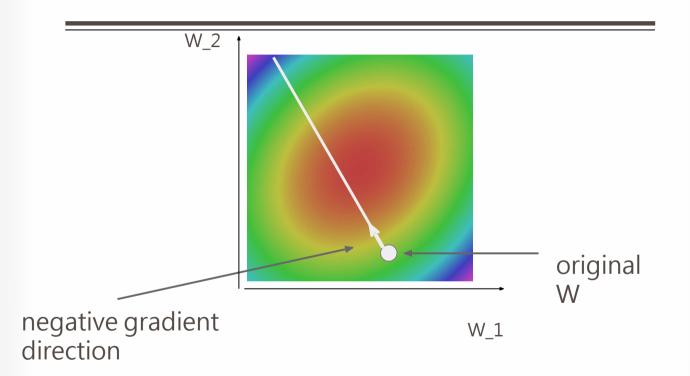

- Numerical gradient: approximate, slow, easy to write
- Analytic gradient: exact, fast, error-prone

 In practice: Always use analytic gradient, but check implementation with numerical gradient. This is called a gradient check.

Gradient Descent

```
# Vanilla Gradient Descent

while True:
    weights_grad = evaluate_gradient(loss_fun, data, weights)
    weights += - step_size * weights_grad # perform parameter update
```

Stochastic Gradient Descent (SGD)

$$L(W) = \frac{1}{N} \sum_{i=1}^{N} L_i(x_i, y_i, W) + \lambda R(W)$$

$$\nabla_W L(W) = \frac{1}{N} \sum_{i=1}^{N} \nabla_W L_i(x_i, y_i, W) + \lambda \nabla_W R(W)$$

Full sum expensive when N is large!

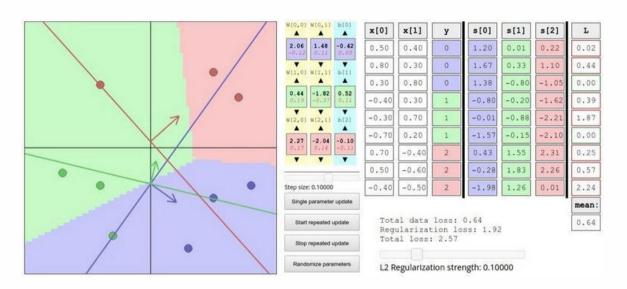

Approximate sum using a minibatch of examples 32 / 64 / 128 common

Vanilla Minibatch Gradient Descent

while True:

```
data_batch = sample_training_data(data, 256) # sample 256 examples
weights_grad = evaluate_gradient(loss_fun, data_batch, weights)
weights += - step_size * weights_grad # perform parameter update
```

FOR YOUR ASSIGNMENT

Aside: Image Features

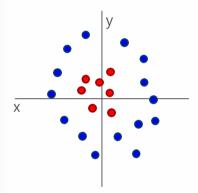

Class scores

Aside: Image Features

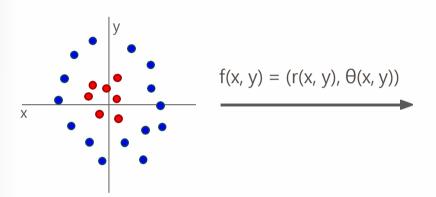

Image Features: Motivation

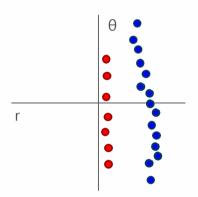

Cannot separate red and blue points with linear classifier

Image Features: Motivation

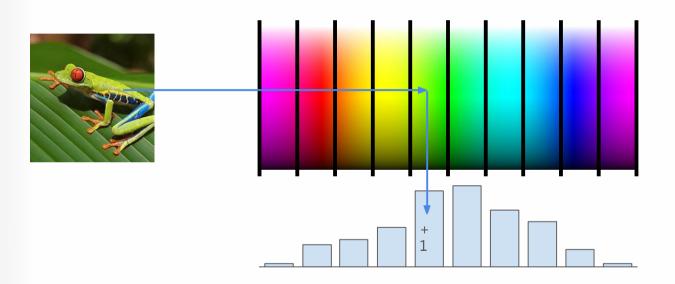

Cannot separate red and blue points with linear classifier

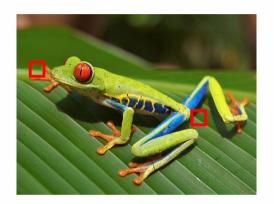

After applying feature transform, points can be separated by linear classifier

Example: Color Histogram

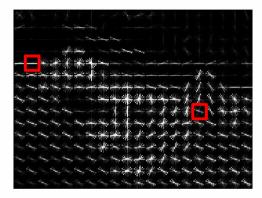

Example: Histogram of Oriented Gradients (HoG)

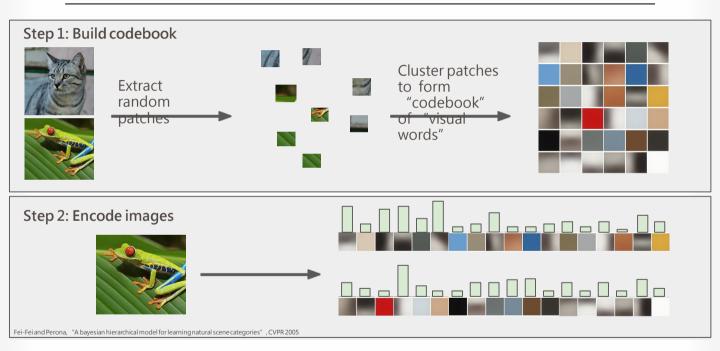

Divide image into 8x8 pixel regions Within each region quantize edge direction into 9 bins

Lowe, "Object recognition from local scale-invariant features", ICCV 1999 Dalal and Triggs, "Histograms of oriented gradients for human detection," CVPR 2005

Example: 320x240 image gets divided into 40x30 bins; in each bin there are 9 numbers so feature vector has 30*40*9 = 10,800 numbers

Example: Bag of Words
